Download

Such information includes, but is not limited to: the product name, the particular product that is being used, the node, the add-on license file, the size of the license file, the time since last re-initialization of the product, product version information, the subscription agreement and any applicable charges. NX can obtain this information either via a remote node or via a local node. For example, if the license file is on a remote node, the NX software program will communicate with that node using a set of communication protocols. If the license file is on a local node, NX software will communicate with that node using a set of communication protocols. A. "Remote Node" means a node connected to NX using the Internet or another network. B. "Local Node" means a node connected to NX using a physical connection such as a telephone line. For example, the licensing information of a node may be provided through use of a data element of type "DOUBLE." This element represents the node's identifier, a status bit, the node's external address (i.e., the IP address and TCP/UDP port number), the node's number of licenses, the time since last initialization of the product and the product version information. By way of example, a license file can contain a node's identifier, a status bit, the node's external address (i.e., the IP address and TCP/UDP port number), the number of licenses, the time since last initialization of the product and the product version information. It should be noted that although a node's identifier is a data element, such data element may, of course, be a data structure. To obtain the licensing information for a specific product and node, NX software must first set the appropriate node's identifier. 3. If the NX software program is located on a remote node, it is necessary to use a protocol such as ICMP echo request to obtain the NX software program's current node identifier. In this example, the NX software program is the server node (i.e., the server to which a remote node is connected). 4. On a local node, the node's identifier may be obtained by using a remote-node-connecting protocol such as TCP/IP and ICMP echo request. To be able to access the licensing information of an add-on product, the add-on product 82157476af
